Project Development Phase

Automating Employee Data

1. Development Overview

The development phase focuses on building the system that automates employee data management. In this phase, the required modules are created and configured to import employee data and link it with incident records.

The system is developed using the ServiceNow platform and uses features such as Import Sets, Transform Maps, and reference fields to automate data handling.

---

2. Employee Data Import Development

Employee data is prepared in an **Excel or CSV file** containing fields such as:

- Employee Name
- Email
- Department
- Manager Name
- Manager Email

This file is uploaded into the system using the **Import Set feature**. The system temporarily stores the imported data in an import table.

---

3. Transform Map Configuration

After importing the data, **Transform Maps** are created to map the fields from the import table to the employee table.

For example:

Import Field	System Field
Employee Name	Name
Email	Email
Department	Department
Manager Name	Manager
Manager Email	Manager Email

This mapping ensures that employee records are automatically created in the system database.

4. Incident Integration Development

The system is configured so that when an **incident is assigned to an employee**, the system automatically retrieves the department manager's email using **reference fields and dot walking**.

This helps support teams contact the appropriate manager quickly when needed.

---

5. Priority Configuration

To improve incident management, default priority values are configured using **dictionary override or system configuration**. This allows the system to automatically assign priority levels based on predefined rules.

6. Testing During Development

During the development phase, the system is tested to ensure that:

- Employee data is imported correctly
- Transform maps work properly
- Manager information appears in incident records
- Incident priority is assigned correctly

7. Development Outcome

After completing the development phase, the system successfully automates the process of importing employee data and linking it with incident management. This reduces manual work, improves data accuracy, and increases the efficiency of the system.
